

Internal Subnet Discovery Guide

Analyst: Bondam Christopher Kweku

Phase 1: Scan Initialization

Initializing high-speed Nmap engine parameters including parallel DNS resolutions.

Figure 1: Nmap parallel script engine init.

Phase 2: Ping Sweep Execution

```
nmap -sn 192.168.1.0/24
```

Broadcasting ICMP echo requests across the Class C private subnet.

Figure 2: Active host blocks responding to sweeps.

The image shows a terminal window on a Kali Linux system. The window title is 'kali@kali: ~'. The menu bar includes 'Session', 'Actions', 'Edit', 'View', and 'Help'. There are two tabs open, both labeled 'kali@kali: ~'. The terminal output displays a series of Nmap scan results for IP addresses 192.168.1.18 through 192.168.1.23. Each entry consists of three lines: 'Host is up (latency)', 'Nmap scan report for [IP]', and 'Host is up (latency)'. The background of the terminal has a dark, abstract pattern.

```
kali@kali: ~  
Session Actions Edit View Help  
kali@kali: ~ kali@kali: ~  
Host is up (0.00089s latency).  
Nmap scan report for 192.168.1.18  
Host is up (0.00087s latency).  
Nmap scan report for 192.168.1.19  
Host is up (0.0025s latency).  
Nmap scan report for 192.168.1.20  
Host is up (0.0022s latency).  
Nmap scan report for 192.168.1.21  
Host is up (0.0011s latency).  
Nmap scan report for 192.168.1.22  
Host is up (0.00086s latency).  
Nmap scan report for 192.168.1.23  
Host is up (0.00070s latency).
```

Figure 3: Sequential active IP addresses discovered on the LAN.
